

# **Motion preservation for Growth Modulation**

Reinhard Zeller, MD, ScD, FRCSC  
Head, Spine Program  
Hospital for Sick Children  
Associate Professor  
University of Toronto

# Disclosure

- Paradigm Spine: consultant
- Spinevision: co-inventor of a spinal instrumentation: royalties

**Why should we strive  
for Motion (and Growth)  
Preservation?**

**Early « In situ fusion » may lead to significant trunk shortening...**

# ...and respiratory deficit!

# Motion Preservation and Growth Modulation through?

- Tethering
  - Vertebral stapling
  - Short convex hemiepiphysiodesis
- Expansion (Distraction)
  - Through repeated surgery
    - Growing rods
    - VEPTR
  - Through motorized devices
- Future perspectives
  - Hydraulic motorized distraction

# Vertebral Stapling?

# F/U needed

- Will we be able to restore motion once those staples are removed?
- Indications are limited
  - Not for aggressive scoliotic deformities
    - Hemiepiphysiodesis is not very efficient in those indications

# « growing rod » with anterior convex fusion

# « Crankshaft » phenomenon and spontaneous posterior fusion

# Rate of distraction? Beware of the posterior tethering effect!

**Repeat distractions with  
a more flexible system?**

Rib fixation?

**Will we be able to  
maintain those results  
up to the end of  
growth?**

Decompensation during the  
growth spurt?

**Frequent distractions  
may help with  
preservation of the  
trunk shape during the  
growth spurt**

Motorized systems?

# Encouraging results but

- How can we avoid loss of fixation at the level of the anchor points?
- How can we supply an efficient powersource over many years?

# Motorized hydraulic system: NADAR

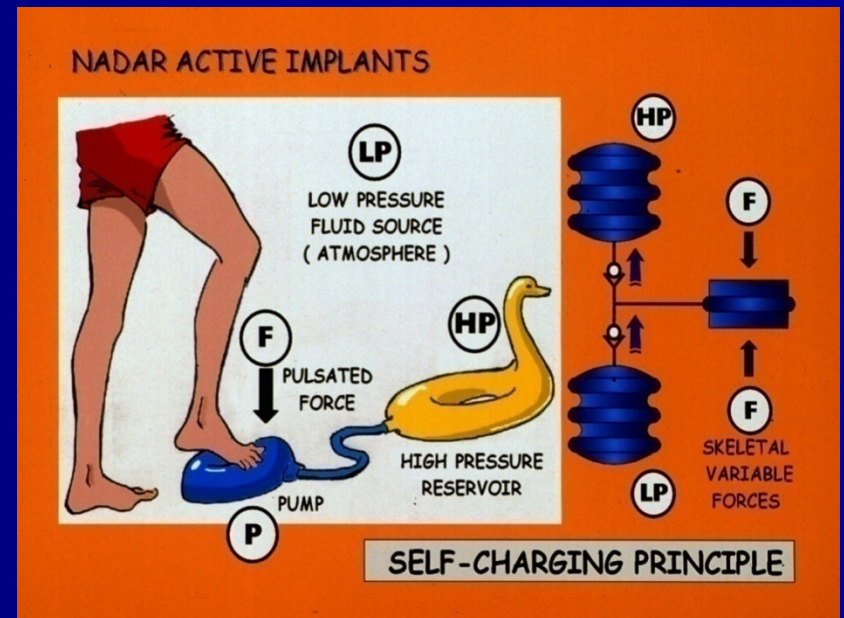

# Fred Zacouto: Inventor of the artificial heart, co-inventor of the pacemaker

# Power source: spinal movement

# Animal experimentation

- 3 implantations (Spanish team)
  - Demonstrating that the system generates a significant power source
    - Generating a scoliotic deformity in a ram
- Privately financed:
  - .....

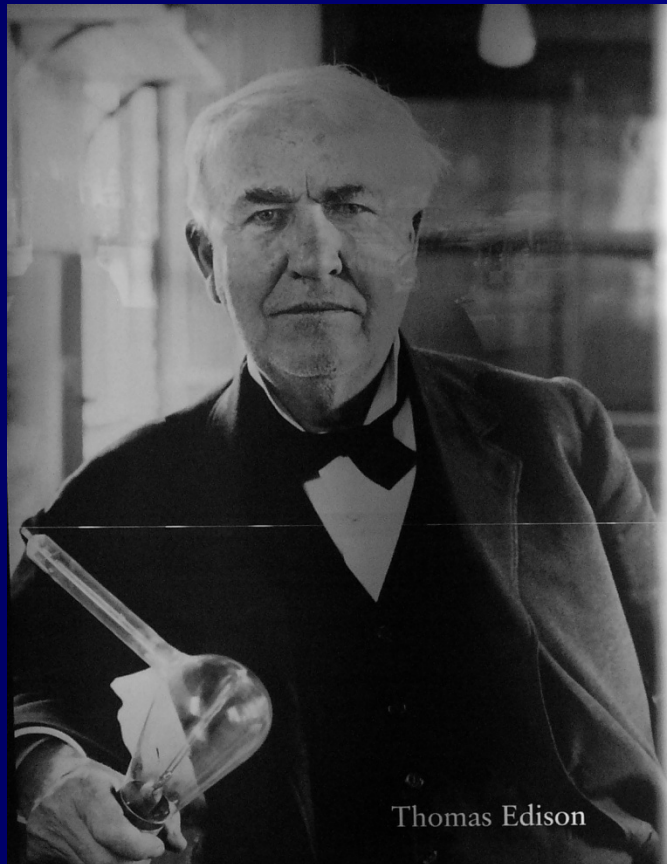

# To be followed....

- Will we be able to protect efficiently the bone anchor sites with a hydraulic damping system?
- How can we solve technical problems like miniaturization, prevention of leakage (microcircuits)?

# Promising technique

A black and white photograph of Thomas Edison, an elderly man with white hair, wearing a dark suit and a bow tie. He is holding a large, glowing incandescent light bulb in his right hand. The background is slightly blurred, showing what appears to be a workshop or laboratory setting.

On the  
10,000th try  
there was  
light.

**OPTIMISM**  
*Pass It On.*
